# The IDEA Framework [1] + Formal Verification

- How can the two strategies be compared? Empirically or is there mathematical evidence?
- Should the two strategies be compared on the fly? Is it even possible?
- Can the formally verified strategy realistically be computed at runtime?

## Synthesized controller: Payoffs?

The robot has two possible choices:  $A_s = \{\text{contact-staff, do-help}\}$

Uppaal Stratego synthesizes a controller for the robot indicating the expected payoff value when choice act  $\in A_s$  is selected in GI or NOT\_GI, indicated as  $U(\text{GI}, \text{act})$  and  $U(\text{NOT\_GI}, \text{act})$ , respectively.

Uppaal optimizes the system's payoff value assuming a certain degree of rationality on the human's side, i.e., parameter r.

For example:

If  $r = 1.0$  (the human is perfectly rational), they developed a shared identity (GI), and the robot instructs them to help, they will help with probability 1 since  $1.3 > 0.7$ .

## Synthesized controller: Payoffs?

!! At runtime (when applying the controller), the robot does not know whether the human is in location GI or NOT\_GI !!

We have an estimate (e.g., through a NN) of  $P(\text{GI})$ ,  $P(\text{NOT\_GI}) = 1 - P(\text{GI})$ .

# Formal Model: How to deal with uncontrollable actions affected by uncertainty?

Re-calibrate the expected payoff value to account for the probability to reach the corresponding state (where act is either call-staff or do-help):

$$u_S(\text{GI}, \text{act}) = U(\text{GI}, \text{act}) \times P(\text{GI})$$

$$u_S(\text{NOT\_GI}, \text{act}) = U(\text{NOT\_GI}, \text{act}) \times (1 - P(\text{GI}))$$

# IMPACT+ Framework for Formalised IDEA agents: Ad-hoc strategy

## **Experiment Settings:**

- **Ad-hoc** Strategy
- **Fixed** (462, 6%) vs. **variable** (150-700, 1-10%) Passengers/Staff Members
- **Time Bound** 20/50/200 s
- **Rationality Degree** 1.0/PI ( $0.33 \times \text{same gender} + 0.33 \times \text{same age} + 0.33 \times \text{same culture}$ )
- **Fall length** 30-600
